

REMARKS

1. The Office Action of January 15, 2003 is hereby acknowledged. This Amendment Under 37 C.F.R. § 1.111 is being mailed by Express Mail, Mail Label No. EV 255344425 US addressed to Mail Stop Fee Amendment, Commissioner for Patents, P.O. Box 1450, Alexandria, Virginia 22313-1450 on May 27, 2003. The shortened statutory period of three (3) months time period for response to this Office Action expired on April 15, 2003. The Applicant has enclosed with this Amendment a Request for Two Month Extension of Time through April 7, 2002 under 37 C.F.R. § 1.136 for this Amendment to be timely filed and has enclosed the required fee of \$205.00. Therefore, the deadline for filing a timely response is now extended to June 15, 2003. Accordingly, this Amendment is timely filed. In the event that the Assistant Commissioner for Patents should determine that any additional extension of time is required for this Amendment to be timely filed and an appropriate fee is due for that extension of time, then the Assistant Commissioner for Patents is hereby authorized to charge Deposit Account Number 18-2222 for such appropriate fee.

2. In the original case, the case had 4 claims of invention of which 3 were independent claims. Through the present amendment, the patent application still has 4 claims of invention of which three are independent claims. Therefore, the present application after the amendment has the same number of total claims and the same number of independent claims as the originally filed case. Therefore, no additional filing fee is due.

3. The Patent Examiner's very detailed analysis of the patent application is acknowledged with very great appreciation. The Examiner's hard work in providing a very detailed Office Action is very much noted and appreciated. In accordance with the Patent Examiner's statements in Section 1 and 2 of the Office Action, the Applicant has restructured the patent application to move portions of the patent applications to different sections. Specifically, the original portion of the patent text which appeared on Page 27, line 23, through Page 28, line

1 4, and Page 28, line 15, through Page 30, line 16, which dealt with the prior art, has been moved
2 to Page 6, after line 7. In addition, the portion of the patent text that really should have been
3 included in the summary of the invention which was on Page 16, line 28, through Page 19, line
4 7, has been moved to Page 7, line 12. Therefore, since there have been extensive amendments
5 to the specification, the Applicant enclosed a clean version and a marked up version as per
6 current 37 C.F.R. § 1.125. No new material has been added and no changes have been made
7 other than the amendments noted above in the Amendment to the Specification section, only the
8 portions of the text have been moved to bring it into consistency with the Examiner's statements
9 under Section 2 concerning arrangement of the specification.

10 The Applicant also acknowledges with appreciation the Examiner's statements in
11 Paragraphs 2, 3 and 4 of the Office Action concerning reviewing the text. The Applicant has
12 carefully reviewed the text and has found one additional typographical mistake in addition to the
13 one that the Examiner cited. The Applicant has made these corrections which are reflected in the
14 enclosed marked up version and clean version of the specification. The Applicant has also
15 carefully checked the specification to be sure that each time the trademarks such as LOOK,
16 SPEEDPLAY, BE-BOP etc. were used, they were also capitalized as instructed by the Examiner.

17
18 4. Therefore, it is believed that all of the Examiner's directives in Paragraphs 1, 2, 3
19 and 4 of the Office Action have been fully complied with.

20
21 5. The Applicant has very carefully studied the Examiner's statements in Paragraph
22 5 of the Office Action concerning the rejection under 35 U.S.C. § 112. The Applicant has
23 amended all of the claims by rewriting the claims to more carefully and precisely define the
24 terms and to be sure there is clear antecedent bases for all of the terms. It is believed that the
25 patent text very clearly discloses and claims what is meant by "a road type bicycle shoe cleat"
26 and "a mountain bicycle type shoe cleat". By way of example, in the original patent text, Page 5,
27 Lines 20 through 28, what is meant by "a road type bicycle shoe cleat" is discussed and
28 illustrated in Figure 8A and 8B. Also referring to Page 26, lines 10 through 28, and Page 27,

1 lines 1 through 5 of the original patent text, there is further discussed another example of “a road
2 type bicycle shoe cleat” and it is illustrated in Figures 9A through 9C. Further, referring to the
3 original text on Page 27, lines 7 through 21, and referring to Figures 10A and 10B, there is
4 discussed what is referred to as “a mountain bicycle type shoe cleat”. Therefore, it is
5 respectfully submitted that “road type bicycle shoe cleat” and “mountain type bicycle shoe cleat”
6 are clearly defined terms which are discussed in both the text and the drawings of the patent
7 application. For consistency, these same terms have been used throughout all the newly revised
8 independent claims 5, 6 and 7. Therefore, it is respectfully submitted that the Examiner’s
9 comments, while very well taken and appreciated, have now been overcome and there is no
10 longer any ambiguity with respect to the phrases of a road type bicycle shoe cleat and a
11 mountain bicycle shoe cleat and these have been used consistently through the revised claims.

12 With respect to the Examiner’s statement that “No antecedent basis is seen for the
13 term, such as, ‘the rear spring-loaded retaining plate of said bottom side’ in claim 1”, this has
14 now been corrected through the revised claims and the revised claims have been very carefully
15 studied to be sure that there is proper antecedent basis for all subsequently used terms.

16 For all of the above reasons, it is respectfully submitted that the newly revised
17 Claims 5 through 8 have overcome the Examiner’s rejection under 35 U.S.C. § 112.

18
19 6. The Applicant has very carefully studied the Examiner’s statements in Paragraph
20 6 of the Office Action wherein the Examiner has rejected the application under 35 U.S.C. § 102
21 on the grounds that the Examiner believes that the present application is anticipated by United
22 States Patent 6,035,743 filed on March 18, 1998 and issued on March 14, 2000 to Gapinski for
23 “MULTI-FUNCTIONAL CLIPLESS PEDAL” (hereafter “Gapinski Patent”). The Applicant
24 believes that the Gapinski Patent shows a totally different type of innovation but before
25 addressing that, the Applicant will deal with a more fundamental basic provision wherein the
26 Applicant believes that the Gapinski Patent should not be cited against the Applicant’s ‘417
27 Application. The Examiner states that “Since Applicant now claims, e.g., ‘a rear spring-loaded
28 retaining plate’ which is not disclosed in SN’022 (referring to Serial No. 08/923,022 filed on

1 September 3, 1997), therefore, the claims in this application are not entitled to the filing date of
2 SN'022. In other words, since: (a) the claims in this application are drawn to new Figs. 18-22 of
3 this application as described on page 30 et seq. of the specification; and (b) these new Figs. 18-
4 22 were not disclosed in SN'022 and SN'561, therefore, these claims are entitled to the filing
5 date of October 10, 2001 of this application only." The Applicant very respectfully disagrees
6 with the Examiner and based upon the modifications that were made by the Applicant to bring
7 the present '417 Application into a more coherent format, it is understood why the Examiner
8 may not have appreciated that the flip-flop pedal as currently being claimed by the Applicant
9 was in fact fully disclosed in the patent application which was filed on September 3, 1997.

10 To facilitate the Examiner's review, the Applicant is also currently submitting
11 with this Amendment, a complete copy of the prosecution history of Patent Application
12 08/923,022.

13 When redoing the present application, in order to make it more consistent and
14 flow better, the Applicant made the following drawing number changes (but did not modify in
15 any way any of the drawings). Specifically, former Figures 6a, 6b, 7a and 7b were changed to
16 Figures 5a, 5b, 6a and 6b in the revised continuation-in-part patent application being considered
17 by this Examiner. Former Figures 5a, 5b, and 5c were now changed to Figures 7a, 7b and 7c.
18 Once again, it is emphasized that the figures have not been changed in any way and no new
19 matter has been added but the numbering of the figures has simply been rearranged in order to
20 make them flow better and more logically in the patent application.

21 Basically, Figures 7a, 7b, and 7c (formerly Figures 5a, 5b and 5c in the originally
22 filed Patent Application 08/923,022 filed on September 3, 1997) essentially disclose the present
23 invention as claimed. Therefore, the disclosure as will be discussed below has a priority date of
24 September 3, 1997 and therefore, the Gapinski Patent is not prior art to the present application.

25 Referring specifically to Figures 5a, 5b and 5c (which correspond to Figures 7a
26 through 7c of the present '417 Application), there is illustrated a bicycle pedal that has two
27 different mechanisms for connecting to two different shoe cleats, one being a road type bicycle
28 shoe cleat and the other being a mountain type bicycle shoe cleat. The top view Figures 5a

1 discloses the pedal for accommodating a road type bicycle shoe cleat. What makes it a road type
2 bicycle shoe cleat is that typically this type of platform connects to a pedal system. A road type
3 is bigger than a mountain bicycle type. Figure 5a is a top view and Figure 5b is a side view of a
4 pedal for connecting to a road type bicycle shoe cleat and Figure 5c is a top plan view of a pedal
5 for connecting to a mountain bicycle type shoe cleat.

6
7 7. The Applicant will now compare what is shown in Figure 18 of the
8 present application to what is shown in Figures 7a through 7c (taken identically from Figures 5a
9 through 5c in the parent case) show that everything that the Applicant is disclosing and claiming
10 in the present '417 Application was in fact disclosed in the original application filed on
11 September 3, 1997. Referring to Figure 18, the flip-flop bicycle pedal 570 comprises a main
12 body 199 extending through a threaded spindle bolt or connector 200. The threaded spindle bolt
13 or connector which we have in the sequence of numbers 7a, 7b and 7c and Figure 18 is
14 threadedly connected to a bicycle pedal crank where the main body is pivotable about a
15 transverse axis 574. The main body has a top or first side 576 and a bottom or second side 578.
16 Top first side 576 is comparable to the views in Figures 7a and 7b and the bottom or second side
17 578 is comparable to view in Figure 7c.

18 The top side 576 is similarly configured to the first prior bicycle pedal 500 (see
19 Fig. 12) and includes a toe cleat clamping mechanism which has a front recess 202 for receiving
20 the front tongue 224 of the first prior art shoe cleat (see 8a and 8b), a rear spring loaded plate
21 204 (please note that 202 and 204 are also shown in Figure 7b) pivotably connected to the main
22 body 199 by a bolt 205 which is shown at the bottom of Figure 7b and an internal spring 580
23 wound around bolt 205. The bolt 205 which is shown in Figure 7b (and originally in Figure 5b
24 from the parent patent text) is shown without the spring but we can examine the original patent
25 text to show that the concept of the spring is clearly disclosed. Referring specifically to the
26 original patent text on Page 9, the first full paragraph reads: "Figure 5a shows a top view of the
27 LOOK compatible flip-flop pedal. The top side consists of a toe clamp (202) which holds the
28 front of the cyclist's LOOK compatible cleat (not shown). A spring plate (204) moves back

1 when the cleat is inserted and snaps forward to lock the cleat on the pedal.” Therefore, it is
2 abundantly clear that the spring action which is talked about is clearly intended and clearly
3 discussed in the patent text. Obviously, it could not spring back in that way unless there was a
4 spring tension that was causing it to spring back as discussed in the text. For purposes of clarity,
5 in Figure 18, the spring 580 has been shown but it is abundantly clear that it is about a bolt 205
6 which was fully disclosed in the original patent text.

7 When a force is applied at a surface 207 as shown in both the first prior art shoe
8 cleat (see Figure 19 and shown in dashed lines), the spring loaded plate 204 moves away from
9 the main body 199 such that the rear tongue 226 (see Figure 20 and shown in dashed lines) of the
10 first prior art shoe cleat falls inside the recess 209. The spring loaded plate springs back into a
11 locking position, thereby locking the first prior art shoe cleat to the top side of the main body of
12 the flip-flop pedal. This entire concept was clearly discussed in the portion of the quoted text
13 from the original patent application filed in September 1997.

14 The bottom side 578 which is the equivalent of Figure 7c (formerly Figure 5c of
15 the parent case) of the flip-flop bicycle pedal 570 is similarly configured with the second prior
16 art bicycle pedal 504 and includes a toe cleat clamping plate or mechanism 212 which is shown
17 in Figures 7c and 5c. The bottom side 570 of the flip-flop bicycle pedal 570 is similarly
18 configured with a second prior art bicycle pedal 504 and includes a toe cleat clamping plate or
19 mechanism 212 (this is shown in the original Figure 5c) which is smaller than the toe cleat
20 clamping mechanism located on the top side 576 and that is also shown. The toe cleat clamping
21 mechanism 212 is mounted to the main body 199 by retaining screws 214 and 218 and this is
22 shown in the original patent drawings from the parent case Figure 5a as retaining screw 214 and
23 the other one, even though not labeled, is also shown in original Figure 5c and has now been
24 numbered as 215 in Figure 7c.

25 The front tongue 512 of the second prior art shoe cleat 510 (see Figure 23) is first
26 inserted into the locking fixture 208. Fixture 208 is shown in Figure 5c and also in now Figure
27 7c. The rear tongue 514 engages with and pushes against the spring loaded retaining plate 216.

28 Further, a spring 582 is held in place by a bolt 211. The bolt is shown in Figure

1 5b. It is mounted on the main body 199 to the flip-flop bicycle pedal 570. The spring 582 is
2 wound around the bolt 211 which we say is shown in Figure 5b. When a force is applied on the
3 spring loaded plate 216 by a second prior art shoe cleat, the spring loaded plate moves away
4 from the main body (see Figure 22) such that the rear tongue 514 of the second prior art shoe
5 cleat falls inside the recess 210 and the spring loaded plate 216 springs back into a locking
6 position, thereby locking the second prior art shoe cleat 510 to the bottom of the main body.
7 Referring once again to the text of the original patent application filed in September 1997, and
8 again referring to Page 9, beginning with the third full paragraph it states "Figure 5c shows a
9 bottom view of the SPD compatible flip-flop pedal. The cleat toe clamp (214) holds the toe of
10 the SPD compatible cleat and the spring loaded heel clamp (208) is pushed back under the
11 downward movement of the cleat and finally springs forward to lock the SPD compatible cleat
12 onto the pedal (213)." Therefore, once again, it is abundantly clear that the spring loaded feature
13 was disclosed and discussed and illustrated in the original patent application and therefore, this
14 concept which was clearly fully illustrated and discussed in the patent application should be
15 awarded the date of the earlier parent case.

16
17 7. Therefore, for all of the above reasons, it is very respectfully submitted that the
18 key features which are being disclosed and claimed in the present invention do have full
19 antecedent support both in terms of the drawings and the patent text in the originally filed case of
20 September 3, 1997 and therefore, should be awarded the earlier filing date and therefore,
21 Gapinski should not be cited as a 35 U.S.C. § 102(e) reference.

22
23 8. The Applicant will now discuss why there are certain key differences between the
24 present invention as claimed and the Gapinski Patent. First, it is abundantly clear that the
25 Gapinski Patent is focusing on a totally different type of attachment device. Specifically, as
26 illustrated in the exploded view of Figure 1 of the Gapinski Patent, what is sought to be attached
27 is a pedal adapter wherein the person fits the shoe inside the pedal adapter 62. That is totally
28 different from the entire concept as disclosed and discussed in the present invention where the

1 cleat is affixed to the shoe and then attached to the present invention flip-flop pedal. In
2 Gapinski, the cleat is not affixed to the shoe but the cleat of Gapinski is attached to a full pedal
3 adapter where the shoe itself is inserted into the pedal adapter. In addition, the fundamental
4 principle by which the cleat is locked onto the adapter is totally different in the Gapinski Patent.
5 Specifically, referring to the Gapinski Patent in Column 3, beginning on line 56 it states "A
6 pivoting member 76, forming part of the locking mechanism structure 77, is positioned on the
7 base member 50 between the front 44 and the rear 46 edges thereof. The pivoting mechanism 76
8 moves between an unlocked position (shown in dash in FIG. 3 and sold in FIG. 4) and a locked
9 position (shown in dash in FIG. 3 and sold in FIG. 4)."

10 Another key difference of the present invention as opposed to the Gapinski Patent
11 is the pivoting mechanism as illustrated in Figure 5 of the Gapinski Patent. As illustrated in
12 Figure 5, the pivoting mechanism has a bolt on the bottom so that the back cleat member rotates
13 away in the horizontal direction in order to lock the back cleat in place on the road type bicycle
14 cleat; whereas in the present invention as disclosed and claimed, the back portion is pushed away
15 through a spring mechanism and latches by a spring action attaching it onto the back clip. That
16 is the reason that they have a spring shown in the horizontal direction in Figure 5 of the Gapinski
17 Patent. Also referring to Figure 3, the Gapinski Patent does not show a spring mechanism on the
18 back of the pivot but instead, shows a solid piece where the cleat slides in. Also referring to
19 Column 5 beginning on line 1 of the Gapinski Patent, it states "The cleat adapter 22 can be
20 removed from the road style clipless structure 26 typically by twisting the rear edge 46 of the
21 cleat outwardly (away from the crank arm to which the pedal is attached) in the lateral plane (of
22 the top surface of the main body of the pedal) with respect to the pedal 20." Therefore, the
23 method by which the cleat is attached and disattached is a rotational mechanism which is why
24 there is the horizontal spring illustrated in Figure 5 of the Gapinski Patent. This is totally
25 different from the method by which the cleat is received and locked in place by the spring action
26 from the rear portion of the flip-flop pedal of the present invention.

27 Therefore, because of the fact that the Gapinski Patent itself should not be cited as
28 prior art for the reasons as set forth above and further because of the fact that the present

1 invention as now disclosed and claimed operates totally differently from the way the cleat is
2 inserted and removed from the flip-flop pedal, the present invention is totally different and
3 discloses key fundamental differences.

4 Further, as is evidenced by the only independent claim of the Gapinski Patent, the
5 third element of Claim 1 recites "a locking mechanism to lock said cleat adapter to said base
6 member, said locking mechanism including a pin extending from said base member and a recess
7 formed on said main body for receiving said pin." This is a key feature of the Gapinski Patent
8 which is not shown or disclosed or claimed in the present invention and therefore, the Gapinski
9 Patent focuses on a totally different type of method of attachment to the flip-flop pedal. Clearly,
10 the method of attachment in the present invention as discussed above wherein the rear portion of
11 the cleat is pushed against the spring loaded rear portion of the flip-flop which then springs back
12 and locks in place is totally different from the sidewise action of the Gapinski Patent and also,
13 from the fact that the Gapinski Patent requires the locking pin to retain it in place. Therefore,
14 Gapinski is totally different from the present invention.

15
16 9. The Examiner also has cited United States Patent 5,692,415 to Lin. Not much is
17 said about Lin in the Gapinski Patent but it is merely cited as being of reference. An
18 examination of the Lin Patent clearly shows very key differences including the following. First,
19 it is not designed to accommodate a road type bicycle shoe cleat and a mountain bicycle type
20 shoe cleat. Further, while it does show some spring action, as stated in the Lin Patent, "FIG. 1
21 shows a prior art bicycle pedal designed for the coupling of the sole of a bicycle shoe. The
22 structure of bicycle pedal comprises two fixed locating plates and two movable locating plates
23 for the coupling of the sole of the bicycle shoe. The movable locating plates are respectively
24 forced toward the fixed locating plates by springs. The spring force of each is controlled by a
25 respective stop plate and a respective screw bolt. This structure of bicycle pedal is complicated,
26 and needs much installation space. When adjusting the spring force, the stop plate tends to fall
27 out of place, causing the springs unable to be forced into place." Therefore, it is clear that the
28 type of device that is being disclosed by Lin shows springs in a different location from the

1 present invention and also obviously did not work. The device that Lin used to solve this
2 problem is a very long complicated device including stop plates as set forth in the very long
3 independent claim. Therefore, the Lin Patent does not disclose or make obvious the present
4 invention as now claimed.

5
6 10. For all of the above reasons, it is respectfully submitted that the present
7 application is now in condition for allowance and issuance of a Notice of Allowance is
8 respectfully solicited.

9 Respectfully submitted,

BICYCLE PEDAL THAT CAN FIT A MULTIPLICITY OF SHOE CLEATS

BACKGROUND OF THE INVENTION

This application is a continuation-in-part of application Serial No. 09/360,561 filed on May 26, 1999, now pending, which is a continuation-in-part of application Serial No. 08/923,022 filed on September 3, 1997, abandoned.

RECEIVED

JUN 02 2003

GROUP 3600

1. Field of the Invention

This invention relates to bicycle pedals and in particular, to pedals that have a multiplicity of shapes that can accommodate a variety of bicycle shoe cleats. Use of the invention allows cyclists using clip-less pedal systems to cycle on a bicycle fitted with these multiple shaped pedals, when the cyclists have a variety of shoe cleat designs on their shoes.

2. Description of the Prior Art

The continuing development of modern bicycles has resulted today in bikes being available to the general public with a wide variety of pedal designs. Early designs of bicycle pedals consisted of a flat pedal shape with a toe frame that fitted most cyclist's shoes, and included a strap or other connecting means that fixed or fastened the toes of the cyclist's shoes to the pedals. Cycling shoes were typically of a running shoe design and were not specifically designed for cycling.

1 In modern bicycle pedal designs this arrangement has been superseded by more precise
2 mechanisms that lock the pedal onto special cleats which are fastened to the base of the cyclist's
3 shoes. These new designs are called clip-less pedal/cleat designs. Using these new designs, the
4 cyclist mounts the bicycle, places his shoe cleat onto the pedal and the pedal/cleat combination
5 snaps or locks together creating a stable connection between the cyclist's feet and the bicycle
6 pedal.

7
8 Various designs of pedal/cleat combinations are presently in use, which either lock
9 rigidly together or allow various degrees of freedom of rotational motion between the pedal and
10 the cleat, depending on the design. Manufacturers of pedals today typically produce pedal
11 designs that require the use of special shoe cleats that lock onto or into their pedals only. This
12 ensures the manufacturer that the cyclist buys their particular combined pedal/cleat products.

13
14 Thus modern cyclists require a particular design of matching shoe cleat to be worn on
15 their cycling shoes in order to fit onto the pedals on their bicycles. Due to the better
16 performance and ease of entry and exit of these new pedal/cleat designs, this is now the
17 generally accepted standard in the case of the cyclist's own bicycle. Individual cyclists fit their
18 preferred pedals onto their bicycles and fit the appropriate cleats onto their cycling shoes.

19
20 In recent years, there has been increasing interest and use of stationary exercise bicycles
21 and many of the companies that manufacture road bicycles or other exercise equipment have
22 also developed a line of stationary exercise bikes to meet this new demand. However, when
23 these same pedal/cleat combinations developed initially for road bicycles are also used on the
24 stationary cycling machines (or spin-bikes as they are known) which are available in gyms or
25 sports clubs, the cyclist is forced to use the appropriate cleat on his bicycle shoes.

26
27 This causes problems, as most cyclists prefer to use a particular brand and design of
28 pedal/cleat combination on their road bicycles, and yet many cyclists have no choice but to

1 purchase a new set of cycling shoes and install cleats that match the gym's spin bike pedals.
2 Alternatively, cyclists have to bring their own pedals to the gym or exercise club and exchange
3 the pedals on the stationary bike with their own so they can use their own shoes and cleats to
4 exercise. This practice is becoming less and less acceptable to gym instructors who do not want
5 different riders to be changing pedals on their exercise bikes.

6
7 Another problem that has arisen on stationary bikes is the breakage of pedal spindles.
8 The pedal spindle is a steel rod that fits inside the pedal center housing with bearings, allowing
9 the pedal to rotate around the spindle. The end of the spindle projects from the side of the pedal
10 and contains a threaded section that is used to connect the pedal to the bicycle crank arm.
11 Breakage of this spindle is extremely rare in outdoor bikes even among world class powerful
12 cyclists and is a phenomenon that occurs quite frequently on stationary bikes probably caused by
13 the higher forces that come to bear on an indoor exercise bike's pedal as explained below.

14
15 Part of this breakage problem of spindles is caused by the fact that the frame of a
16 stationary bike is more rigid than the frame of a street or racing bicycle and so there is less 'give'
17 or flex available in the frame of the stationary bike. Also, the frame of all exercise bikes sits on
18 the floor supported at four corners by rollers or foot stands. The frame itself is quite rigid when
19 compared to a road bike, since weight is not a premium on an exercise bike. Thus when a rider
20 bears down heavily on one pedal of the stationary bike, the bike does not rotate in the same
21 direction as the pedal load nor does the frame flex, and so all of the extra load is carried in
22 bending by the pedal spindle.

23
24 Repeated over-stressing of the spindle in this manner results in spindle failures causing
25 the pedal to suddenly break off the spin bike pedal crank and with the attendant danger of injury
26 to the rider. In some exercise clubs or gyms, pedal spindle breakage is a common occurrence
27 and has increased the costs of maintenance and downtime of equipment and the number of spare
28 parts that must be carried to keep the bikes in good running condition. Exercise clubs are also

1 very aware of the increased possibility of injury that can occur when one of the spindles breaks,
2 thus increasing their liability risks.

3
4 Manufacturers of spin bikes generally ensure that their own designs of pedal/cleat
5 combinations are interchangeable. However, there is no interest on the part of these
6 manufacturers to make their pedal/cleat designs compatible with any of their competitor's
7 designs. This has created a serious inconvenience and difficulty in the use of spin bikes, which
8 are used by a wide variety of cyclists and non-cyclists who are clients of a gym or exercise clubs.
9 The clients of the gym or club wish to use their own particular brand of pedal/cleats and the gym
10 can only offer a very limited selection.

11
12 Generally the exercise clubs offer the pedals sold to them with the exercise or spin bike
13 by the particular spin bike manufacturer. To get around the problem, the gym may have to
14 purchase spin bikes from a number of suppliers or change the pedals on their existing bikes to
15 accommodate a wider variety of user preferences.

16
17 There is no known prior art in the field of pedal/cleat designs that fully addresses the
18 pedal/cleat and spindle problems discussed above. In an earlier patent application, the present
19 inventor disclosed a design for a flip-flop pedal, which is a first step to address the problem. The
20 earlier application disclosed a pedal design which utilized both sides of the pedal surfaces so that
21 one side matches a pedal type, embodied in the popular brand known as LOOK (the generic term
22 for LOOK is a road bicycle style pedal). The other side of the pedal surface matches a pedal
23 type embodied in the popular brand known as SPD (the generic term for SPD is a mountain
24 bicycle style pedal). This earlier design of a LOOK/SPD (road/mountain) flip-flop pedal is
25 disclosed and illustrated in the earlier application number 08/923,022.

26
27 LOOK is a French company that makes a variety of products, one of which is a line of
28 bicycle pedals and matching cleats. SPD is also a matching pedal/cleat design for bicycles made

1 by the Shimano Pedaling Device Co., of Japan. The present invention also includes special
2 adapters that also accommodate cleat designs produced and sold by the SPEEDPLAY Company
3 of San Diego, California and in particular their cleat designs known as SPEEDPLAY X-Pedal
4 (generic term is a road style pedal) and SPEEDPLAY Frog (generic term is a mountain style
5 pedal). By this combination of flip-flop pedal and adapters, bicycles and mainly spin-bikes
6 fitted with the invention can accommodate a very large majority of cyclists and shoe cleat
7 designs.

8
9 In the art there is a special pedal adapter sold by a manufacturer called INSTEP (road)
10 that fits onto both a LOOK (road) and an SPD (mountain) style pedal. The INSTEP (road) brand
11 adapter is made by Winwood Company of Denver, Colorado. Thus a cyclist wearing running
12 shoes which do not have any bicycle shoe type sole cleats, can lock his running shoe into place
13 on the INSTEP (road) adapter which in turn is mounted on a spin bike with a LOOK (road) style
14 pedal. In this manner, a cyclist wearing running shoes can use a stationary spin bike, which are
15 fitted with LOOK or SPD style pedals (road or mountain). This INSTEP (road) adapter is an
16 attempt to address part of the problem discussed above, but does not take it to the level of
17 invention described in the present application. Further, the INSTEP (road) adapter is essentially
18 a toe-strap design and so represents a step backwards to the early unsatisfactory toe-strap designs
19 used on bicycles many years ago.

20
21 Figure 8a is a prior art top plan view of a standard LOOK (road) style
22 shoe cleat that is attached to the sole of a cyclist's shoe. Three rectangular holes (221,
23 222, 223) are used to attach the cleat to the shoe sole (not shown). The top surface (288)
24 of the shoe cleat is curved to fit the typical cycling shoe sole. All three rectangular holes
25 have a recessed edge (227) which accommodates a rectangular washer (252 in Figure
26 8b). One central rectangular hole (225) is used to hold a rubber bumper (not shown)
27 which stops the cleat from rattling when loosely fitted to the sole of the cyclist's shoe.
28 The rear front tongue (~~226~~) (224) of the cleat fits under the front recess (202 in Figures

1 spring-loaded retaining plate (202 204 in Figures 7a and 7b).

2
3 Figure 8b is a prior art exploded and cross-sectional view taken along line 8b-8b of the
4 standard LOOK (road) style shoe cleat shown in Figure 8a. The front and rear tongues (224 and
5 226) are shown. Three retaining washers (252 only one is shown) fit in the recesses (227) shown
6 in Figure 8a. Three screws (250 only one is shown) hold the cleat in place on the cycling shoe
7 (not shown) by passing through the washers (252) and through the cleat holes (221, 222, 223 in
8 Figure 8a) and engaging in threaded holes in the base of the cycling shoe (not shown).

9
10 Figure 11 is a view of a prior art INSTEP LOOK (road) style Pedal Adapter. The adapter
11 body (300) is similar in shape to a standard LOOK (road) style cleat (Figures 8a and 8b), with a
12 front tongue (306) and a rear tongue (305) identical to the front and rear tongues of a LOOK
13 (road) style cleat. Thus the INSTEP (road) adapter can be locked onto a LOOK (road) style
14 pedal. The toe-straps (301) are connected to an arch strap (302) through a common connector
15 plate (307). The arch strap (302) is attached to the adapter body (300) in an adjustable manner
16 (not shown). The cyclist inserts his running shoe into the cage consisting of the toe-straps and
17 the arch strap and the upper surface (308) of the adapter base (300), thus forming an attachment
18 between his running shoe and the INSTEP (road) adapter, which in turn, is connected to the
19 pedal.

20
21 Referring to Figure 12, there is shown a prior art of a first conventional type bicycle
22 pedal 500 which is known in the art as LOOK bicycle pedal. This first prior art bicycle pedal
23 500 includes a toe or first retaining section 501, a rear or second spring-loaded plate 502 and a
24 threaded spindle connector 503 which is connected to the bicycle pedal crank (not shown). The
25 toe retaining section 501 holds the front 224 of a prior art of a first conventional type shoe cleat
26 (see Figure 8a) while the rear spring-loaded plate 502 moves away from the body of the pedal
27 when the first prior art shoe cleat is inserted and the rear spring-loaded plate snaps back to lock
28 the shoe cleat on the pedal 500.

1 Referring to Figures 13 and 14, there is shown a prior art of a second conventional type
2 bicycle pedal 504 which is known in the art as SPD bicycle pedal. This second prior art bicycle
3 pedal 504 includes a front tongue recess 505, a rear tongue spring-loaded plate 506 and a
4 threaded spindle connector 507 which is connected to the bicycle pedal crank (not shown). The
5 spring-loaded retaining plate 506 is held in place by a winding spring 508 and secured to the
6 body of the pedal 504 by a bolt 509. Referring to Figure 23, a front tongue 512 of a second prior
7 art type shoe cleat 510 is first inserted into the front tongue recess 505 and then the rear tongue
8 514 of the second prior art shoe cleat 510 pushes against the spring-loaded plate 506, causing the
9 plate 506 to move away from the body of the pedal and once in place the spring-loaded retaining
10 plate 506 moves back into position and securely locks the shoe cleat to the pedal 504.

11
12 Referring to Figure 15, there is shown a prior art of a third conventional type bicycle
13 pedal 516 which is known in the art as SPEEDPLAY "X" bicycle pedal. This second prior art
14 bicycle pedal 516 includes a circular base 518, a metal bow-tie shaped plate 520 which is
15 mounted to the base 518 and held by two screws 522, two grooves 524 located on opposites and
16 parallel to a threaded spindle connector 526 which is connected to the bicycle pedal crank (not
17 shown). Referring to Figure 24, there is shown a prior art of a third conventional type shoe cleat
18 528 which correspondingly matches with the third prior art bicycle pedal 516. The shoe cleat
19 528 includes a circular shaped recess 530 which correspondingly matches the circular base 518
20 of the third prior art bicycle pedal 516 and two opposite parallel rods 532 almost extending the
21 diameter of the recess 530. The third prior art shoe cleat is positioned onto of the third prior art
22 bicycle pedal 516 such that the recess 530 encompass the base 518 and then the two parallel rods
23 532 engage with the two grooves 524 to secure the third prior art shoe cleat 528 to the third prior
24 art pedal 516.

25
26 Referring to Figure 16, there is shown a prior art of a fourth conventional type bicycle
27 pedal 534 which is known in the art as SPEEDPLAY frog bicycle pedal. This fourth prior art
28 bicycle pedal 534 includes a circular metal ring 536 mounted and secured to a protruding base

1 538 by two screws 540, and a threaded spindle connector 537 which is connected to the bicycle
2 pedal crank (not shown). A sloped ramp 542 is formed with the protruding base 538, which
3 allows disengagement of the fourth prior art shoe cleat 544 shown in Figure 25. When the
4 cyclist rotates his or her shoe toward the bicycle's frame, two protruding lugs 546 on each side
5 of the metal ring 536 are engaged by a pair of retaining flanges 548 to secure the fourth prior art
6 shoe cleat 544 (see Figure 25) thereto. A stopping flange 550 is also provided and engages with
7 the sloped ramp 543 to stop the rotation of the fourth prior art shoe cleat 544, thereby fastening
8 the fourth prior art shoe cleat to the fourth prior art bicycle pedal.

9
10 Referring to Figure 17, there is shown a prior art of a fifth conventional type bicycle
11 pedal 552 which is known in the art as BE-BOP bicycle pedal. This fifth prior art bicycle pedal
12 552 includes a pair of spaced apart opposite generally circular flanges 554 which form the
13 attachment mechanism of the pedal, and a threaded spindle connector 547 which is connected to
14 the bicycle pedal crank (not shown) and sandwiched between the circular flanges 554. Referring
15 to Figure 26, there is shown a prior art of a fifth conventional type shoe cleat 556 which
16 correspondingly matches with the fifth prior art bicycle pedal 552. The shoe cleat 556 includes a
17 circular shaped recess 558 which correspondingly matches with either one of the pair of circular
18 flanges 554 of the fifth prior art bicycle pedal 552. The fifth prior art shoe cleat 552 is
19 positioned onto of the fifth prior art bicycle pedal 516 such that the two opposite flanges 560
20 engage with the circular flange 554 of the fifth prior art bicycle pedal to secure the fifth prior art
21 shoe cleat 556 to the fifth prior art pedal 552.

SUMMARY OF THE INVENTION

The present invention is a method and device for improving the fitting of a cyclist to a bicycle which takes into account key aspects of the physiology of the cyclist's body and in particular certain intrinsic structural relationships of the human foot and knee, which invention and method when applied to the fitting of a cyclist on a bicycle results primarily in improved comfort of the cyclist and a reduction in fatigue while cycling.

Tests have also shown that the cyclist, when fitted to his bicycle using the present invention, experiences a reduction in oxygen consumption and a decrease in heart rate while pedaling at a submaximal level and an increase in power applied to the pedals.

The present invention addresses the problem of fitting in a new way. It starts with the position of the cyclist's foot on the pedals and works up the legs to the torso and the hands. The present invention focuses first on the fitting (or positioning) of the cyclist's foot, which is the point where power is applied to the bicycle pedal by the cyclist. An object and advantage of the present invention compared to the current art is the addition of carefully selected wedges to the base of the cyclists shoe, generally under the cleat, which rotates the shoe to match the natural varus or valgus condition of the cyclist's forefoot. This improvement along with better hand placement on the handlebars and the use of specially designed hand grips, has been found by testing to allow an increase in power applied by the cyclist to the pedals for the same amount of energy expended by the cyclist.

Further, the addition of these wedges removes the tendency for the cyclist's knee to move in a lateral direction, to one side then the other, as seen when viewing the cyclist from the front during a complete pedal rotation. Another object of the present invention is the removal of this lateral (sideways) deflections of the knee joint, or rotational knee movement, when viewed from in front of the cyclist, which reduces the sideways strain on muscles and tendons in the leg and

1 foot which in turn reduces fatigue while cycling.

2
3 Another object and advantage of the present fitting invention is to lock the cyclist's shoe
4 onto the pedal fitting device so that full power can be applied by the cyclist throughout the entire
5 rotation of the pedals so that correct fitting measurements can be made. In the current art of
6 pedal mounted devices which are used for fitting a cyclist to a bicycle, the cleat of the cyclist's
7 shoe sits inside an open cavity on the top of the device, designed such that the cyclist cannot
8 apply any upward force or apply full power to the pedal through the cleat, otherwise the cleat
9 comes out of engagement with the pedal mounted device. The present invention locks the cleat
10 onto the pedal mounted device in a manner that simulates an actual locked cleat/pedal condition.

11
12 Another object of the present invention is to avoid the overuse and asymmetric muscular
13 development that occurs when the cyclist's forefoot is forced into a flat position in relation to the
14 pedal as occurs in the current art. When the forefoot is forced into the flat position, the cyclist's
15 knee is pulled in or out of alignment which also causes the patella to be pulled, resulting in over
16 development of the muscles attached to the patella, such as the vastus lateralis muscle on the
17 outside of the cyclist's leg, and underdevelopment of the vastus medialis muscle on the inside of
18 the leg.

19
20 A measurement has been made of the amount of lateral or sideways movement that
21 occurs in a knee when cycling with a flat forefoot condition as is the current standard in the art.
22 The knee's sideways movement was as much as 2 inches side to side. In a 50 mile distance with
23 a cyclist pedaling at 82.5 rpm and a speed of 15 miles per hour, the knee actually travels an extra
24 12.5 miles side to side.

25
26 Significant inertial forces are also created in the leg of the cyclist by the misaligned
27 forefoot, which then continuously changes the horizontal location of the cyclist's knee during the
28 pedal rotation. The extra energy required to supply this motion is considerable when compared

1 with a knee which is moving in the vertical direction only, with no sideways motion.

2
3 It is another object and advantage of the present invention to minimize this wasted
4 energy by adding wedges under the cyclist's shoe such that the inside sole of the cyclist's shoe is
5 at the same angle as his natural forefoot angle or cant thus eliminating unnecessary horizontal
6 movement of the knee.

7
8 Another object and advantage of the present invention is the adjustment of the cyclist's
9 shoe to account for the forefoot cant angle, which spreads the pressure generated on the sole of
10 the cyclist's foot when force is applied to the pedal through the sole of the shoe and the cleat in a
11 more optimum and natural manner. The metatarsal heads of the 5 digits will have the correct
12 distribution of load.

13
14 If the forefoot is forced into the flat position, as in the current art, there is already a
15 misalignment of force applied to the foot sole through the metatarsal heads, or the balls of the
16 foot, which can cause pain and discomfort in the outer portion of the foot. Cyclists who have
17 been fitted with the current art devices which create a flattened forefeet condition on the pedal
18 had previously reported their feet 'going to sleep' during cycling. When fitted according to the
19 method of the present invention, cyclists have reported greatly improved feet conditions during
20 and after a race.

21
22 The invention also measures and corrects for the natural angle that exists between the
23 heel and forepart of the human foot in the neutral or relaxed position by the use of angled
24 wedges positioned under the sole of the cyclist's shoe, thus holding the foot on the pedals in a
25 neutral, relaxed position. This correction reduces the lateral or side-to-side motion of the
26 cyclist's knee or patella when cycling. This reduced side-to-side motion of the knee, and
27 correspondingly reduced rotation of the tibia, contributes to a reduction in fatigue and also
28 reduced oxygen consumption by the cyclist. The invention also results in increased power
applied by the cyclist to the bicycle pedal, thus improving his cycling performance.

1 Proper fitting allows cyclists to be more comfortable, have better energy conservation,
2 perform up to their potential and prevent the overuse injuries to their bodies that can result from
3 poor fitting of the cyclist to the bicycle.

4
5 Some of the many advantages of the present invention when used on exercise bikes and
6 other cycling equipment are:

- 7 (a) it includes a stronger spindle that greatly reduces the frequency of breakage that
8 commonly occurs on stationary exercise or spin bikes.
- 9 (b) it allows the immediate use of an exercise bike by the majority of cyclists who
10 wear shoe cleats made by LOOK (road style pedal), SPD (mountain style pedal)
11 and SPEEDPLAY X-pedal (road style pedal) or SPEEDPLAY Frog (mountain
12 style pedal).
- 13 (c) exercise clubs do not have to inventory a wide variety of pedals for their exercise
14 bikes to meet the needs of their clients.
- 15 (d) exercise clubs can standardize their exercise bikes to one type of pedal design
16 which will now fit the largest majority of rider's bicycle shoes.
- 17 (e) the rider can wear his favorite cycling shoes and cleat type, while exercising in
18 the gym without having to change anything.
- 19 (f) the rider does not have to carry a pedal wrench and spare pedals to the gym when
20 he goes to exercise on the gym's exercise bikes.
- 21 (g) the rider does not have to change the pedals on the gym's exercise bike to fit his
22 shoe cleats before he can ride the exercise bike.
- 23 (h) sports and exercise clubs can offer a wide combination of pedal/cleat designs on
24 all their exercise bikes, while fitting all of their bikes with only the flip-flop
25 pedals and adapters of the present invention.
- 26 (i) the frequency of breakage of pedal spindles is reduced when the invention is used
27 on exercise bikes.
- 28 (j) the sports club does not have to carry such a large inventory of spare pedals in the

1 event of breakage of pedal spindles.

2 (k) maintenance of exercise bikes is reduced due to the more reliable pedal-spindles
3 of the invention.

4 (l) the risk of liability to the sports club is reduced due to the reduction of injuries
5 associated with breakage of the pedal spindles.

6 (m) it allows the sports club to advertise their bikes to a broader range of public.

7 (n) it reduces the occurrence of pedal crank-thread stripping on exercise bikes in
8 gyms, which is caused by too frequent change of pedals by various riders.

9 (o) individuals may purchase their own flip-flop pedals and adapters and bring them
10 for use at an exercise club which has not purchased these pedals for their exercise
11 bikes, and so individuals can exercise wearing their own preferred cycle shoes.

12
13 Accordingly, it can be seen that the pedal and pedal adapters of the present invention can
14 accommodate a wide variety of the bicycle shoe sole cleats in use today. By accommodating the
15 use of bicycle shoes fitted with LOOK (road), SPD (mountain), SPEEDPLAY (road) X-Pedal
16 and SPEEDPLAY (mountain) Frog shoe cleats, the invention covers about 95% of all of the
17 cleat designs presently in use on spin bikes and on road bikes. In addition, use of the invention
18 will allow exercise clubs to offer their clients a wide variety of options in pedal/shoe cleats so
19 that they can use their favorite shoes at the gym without having to change their shoes or the
20 cleats that are already on their shoes. The invention will allow the exercise clubs to minimize
21 costs, as they will no longer have to purchase a variety of extra pedals not offered by individual
22 manufacturers.

23
24 Although the invention disclosed above contains many specifics, these should not be
25 construed as limiting the scope of the invention but as merely providing illustrations of some of
26 the presently preferred embodiments of the invention. For example, the flip-flop pedal can have
27 other shapes, as long as the connecting surfaces are compatible with LOOK (road) and SPD
28 (mountain). Also, the adapter plates to accommodate the two types of SPEEDPLAY (road)

1 pedal cleats can also be designed to fit onto an SPD (mountain) style pedal rather than the
2 preferred LOOK (road) style pedal, etc. Thus the scope of the invention should be determined
3 by the appended claims and their legal equivalents, rather than by the limitations suggested in
4 the examples given.

5
6 Further novel features and other objects of the present invention will become apparent
7 from the following detailed description, discussion and the appended claims, taken in
8 conjunction with the drawings.

BRIEF DESCRIPTION OF THE DRAWINGS

Referring particularly to the drawings for the purpose of illustration only and not limitation, there is illustrated:

Figure 1 is a cross-sectional view of a pedal fitting device.

Figure 2 is a cross-sectional view taken along line 2-2 of Figure 1.

Figure 3 is a skeletal section of the cyclist's lower body.

Figure 4a is a top view of a handle bar fitting device.

Figure 4b is a side view of a handle bar fitting device.

Figures 5a and 5b show views of a modified Allen head screw for securing cleats.

Figure 6a shows a side view of a device for measuring the foot cant angle.

Figure 6b shows a front view of a device for measuring the foot cant angle.

Figure 7a is a top view of a LOOK/SPD (road/mountain) flip-flop pedal.

Figure 7b is a side view of a LOOK/SPD (road/mountain) flip-flop pedal.

Figure 7c is bottom view of a LOOK/SPD (road/mountain) flip-flop pedal.

Figure 8a is a prior art, showing a top view of a standard LOOK (road) style shoe cleat.

1 Figure 8b is a prior art exploded and partial cross-sectional view taken along line 8b-8b
2 of Figure 8a.

3
4 Figure 9a is a top view of a SPEEDPLAY (road) X-Pedal cleat adapter.

5
6 Figure 9b is a cross-sectional view taken along line 9b-9b of Figure 9a.

7
8 Figure 9c is a side view of a SPEEDPLAY (road) X-Pedal Cleat Adapter being fitted into
9 the LOOK (road) style side of a flip-flop pedal.

10
11 Figure 10a is a top view of a SPEEDPLAY (mountain) Frog Cleat Adapter.

12
13 Figure 10b is a side view partially sectioned of a SPEEDPLAY (mountain) Frog Cleat
14 Adapter.

15
16 Figure 11 is a perspective view of a prior art of a INSTEP LOOK (road) style Pedal
17 Adapter.

18
19 FIG. 12 is a perspective view of a prior art of a first conventional type bicycle pedal.

20
21 FIG. 13 is a perspective view of a prior art of a second conventional type bicycle pedal.

22
23 FIG. 14 is a top plan view of the second prior art bicycle pedal shown in FIG. 13.

24
25 FIG. 15 is a perspective view of a prior art of a third conventional type bicycle pedal.

26
27 FIG. 16 is a perspective view of a prior art of a fourth conventional type bicycle pedal.

1 **DETAILED DESCRIPTION OF THE PREFERRED EMBODIMENTS**

2
3 Although specific embodiments of the present invention will now be described with
4 reference to the drawings, it should be understood that such embodiments are by way of example
5 only and merely illustrative of but a small number of the many possible specific embodiments
6 which can represent applications of the principles of the present invention. Various changes and
7 modifications obvious to one skilled in the art to which the present invention pertains are
8 deemed to be within the spirit, scope and contemplation of the present invention as further
9 defined in the appended claims.

10
11 The sport of cycling involves the interaction of a highly adaptable human body and a
12 semi-adjustable mechanical device called a bicycle. The degree of fit between these two can
13 have a profound effect on the performance of the body-bicycle combination. A common
14 denominator of cyclists who enjoy and excel at the sport of cycling is an efficient fit between the
15 body of the cyclist and their individual bicycle.

16
17 It is well known in the art of fitting a cyclist to a bicycle, that the lengths of various limbs
18 and limb sections of the cyclist's body, his or her trunk dimensions, shoulder width, hand size
19 and overall body flexibility and also the physical dimensions of the frame of the bicycle and the
20 location of the seat, the handlebars and the pedals, must be fitted or matched together for the
21 cyclist to achieve good performance and comfort while cycling. Injuries can still occur even
22 with the present art of fitting and a painful knee condition known as chondromalacia patellae is
23 still common among competitive cyclists as well as other overuse injuries. Overuse injuries are
24 injuries caused by repetitive exertion of a body part when that body part is out of correct
25 alignment as occurs using standard pedals and cleats.

26
27 Proper fitting allows the cyclist to be more comfortable, have better energy conservation,
28 perform up to their potential and prevent overuse injuries to their bodies that can result from

1 poor fitting of the cyclist to the bicycle.

2
3 The present invention takes the art of fitting a cyclist to a bicycle to a more advanced
4 level, whereby certain key aspects of the physiology of the foot of the human body are also
5 addressed during the fitting procedure, as well as proper hand placement on the handlebars and
6 the shape and placement of the hand grip used. These additional fitting factors result in
7 noticeably improved comfort for the cyclist and in measurable improvements in the application
8 of power to the pedal of the bicycle and reduced fatigue, when compared to the present art.

9
10 In an experiment with 5 cyclists at the University of Auburn, using the present invention
11 and method a power increase average of 2% was measured. This is a very significant increase in
12 power as one skilled in the art of cycling knows and can make a very significant difference in a
13 cyclist's time during a race or contest.

14
15 The key aspect of the physiology of the human foot that is integrated into the present
16 invention and which is not known in the art, is the fact that about 93% of cyclists have a distinct
17 angular displacement, or cant, of the forefoot in relation to the heel, when the forefoot is in its
18 neutral or most stable, relaxed position. In 87% of cyclists, this angular displacement or cant of
19 the forefoot is toward the outside of the forefoot (called "forefoot varus") and in 6% of the study
20 group, the displacement angle is towards the inside of the forefoot or forefoot valgus. In only
21 4% of cyclists, the displacement angle or cant is essentially zero.

22
23 Up until now, the fitting methods used for cyclists and their bicycles have been based on
24 a number of standard measurements, none of which took into account this aforementioned cant
25 angle of the forefoot or the placement of the hands, grip shape and placement on the handlebars.
26 These current fitting methods use devices which attach onto standard pedal spindles, to steer
27 tubes and to handlebars, and these devices allow adjustment of certain key dimensions of the
28 cyclist's bicycle in relation to certain dimensions of the cyclist's body.

1 For example, the bicycle pedal-to-seat dimension in the vertical and axial fore and aft
2 planes must be adjusted to the cyclist's leg length and his trunk position must be taken into
3 account when selecting the handlebars' vertical and lateral positions. It is well known in the art
4 that there is an optimum angle between the femur and the tibia of the cyclist's leg and this angle
5 should be in the range of 25 to 35 degrees of flexure from the straight position, measured when
6 the pedal is in the lowest or bottom-dead-center position.

7
8 If the distance from the seat in relation to the pedal at its lowest position is too short, this
9 leg angle is more than 35 degrees, causing the cyclist's knee to be flexed too much at the point
10 of highest force in the pedal stroke, thus generating excessive pressure across the patellofemoral
11 joint. Note that the seat should be parallel to the top tube of the bicycle frame when establishing
12 the correct leg angle.

13
14 In the fitting of the cyclist's foot position, the currently existing fitting methods used in
15 the art are limited in scope and adjust the cyclist's shoe toe-in or toe-out position by rotation of
16 the cycling shoe cleat and/or move the position of the cleat fore and aft on the shoe sole. Also,
17 no adjustment for hand position or hand grip shape was used, only a tube shaped bar is used and
18 no other factor is addressed. Improper hand placement can cause discomfort in the wrist, which
19 translates through the arm up to the shoulders and neck, causing excessive discomfort and
20 fatigue in these areas.

21
22 No allowance is made in the art for the natural varus or valgus of the forefoot described
23 above and the shoe is locked in the flat position onto the pedal. This causes the subtalar joint
24 between the foot and the ankle which acts as a torque converter to transform the rolling motion
25 of the forefoot into a vertical rotation of the leg, imparting a torque stress to the knee joint,
26 which in turn pulls the knee out of its correct position.

27
28 ~~The present invention addresses the problem of fitting in a new way. It starts with the~~

1 position of the cyclist's foot on the pedals and works up the legs to the torso and the hands. The
2 present invention focuses first on the fitting (or positioning) of the cyclist's foot, which is the
3 point where power is applied to the bicycle pedal by the cyclist. An object and advantage of the
4 present invention compared to the current art is the addition of carefully selected wedges to the
5 base of the cyclist's shoe, generally under the cleat, which rotates the shoe to match the natural
6 varus or valgus condition of the cyclist's forefoot. This improvement along with better hand
7 placement on the handlebars and the use of specially designed hand grips, has been found by
8 testing to allow an increase in power applied by the cyclist to the pedals for the same amount of
9 energy expended by the cyclist.

10
11 ——— Further, the addition of these wedges removes the tendency for the cyclist's knee to move
12 in a lateral direction, to one side then the other, as seen when viewing the cyclist from the front
13 during a complete pedal rotation. Another object of the present invention is the removal of this
14 lateral (sideways) deflections of the knee joint, or rotational knee movement, when viewed from
15 in front of the cyclist, which reduces the sideways strain on muscles and tendons in the leg and
16 foot which in turn reduces fatigue while cycling.

17
18 ——— Another object and advantage of the present fitting invention is to lock the cyclist's shoe
19 onto the pedal fitting device so that full power can be applied by the cyclist throughout the entire
20 rotation of the pedals so that correct fitting measurements can be made. In the current art of
21 pedal mounted devices which are used for fitting a cyclist to a bicycle, the cleat of the cyclist's
22 shoe sits inside an open cavity on the top of the device, designed such that the cyclist cannot
23 apply any upward force or apply full power to the pedal through the cleat, otherwise the cleat
24 comes out of engagement with the pedal mounted device. The present invention locks the cleat
25 onto the pedal mounted device in a manner that simulates an actual locked cleat/pedal condition.

26
27 ——— Another object of the present invention is to avoid the overuse and asymmetric muscular
28 development that occurs when the cyclist's forefoot is forced into a flat position in relation to the

1 pedal as occurs in the current art. When the forefoot is forced into the flat position, the cyclist's
2 knee is pulled in or out of alignment which also causes the patella to be pulled, resulting in over
3 development of the muscles attached to the patella, such as the vastus lateralis muscle on the
4 outside of the cyclist's leg, and underdevelopment of the vastus medialis muscle on the inside of
5 the leg.

6
7 ——— A measurement has been made of the amount of lateral or sideways movement that
8 occurs in a knee when cycling with a flat forefoot condition as is the current standard in the art.
9 The knee's sideways movement was as much as 2 inches side to side. In a 50 mile distance with
10 a cyclist pedaling at 82.5 rpm and a speed of 15 miles per hour, the knee actually travels an extra
11 12.5 miles side to side.

12
13 ——— Significant inertial forces are also created in the leg of the cyclist by the misaligned
14 forefoot, which then continuously changes the horizontal location of the cyclist's knee during the
15 pedal rotation. The extra energy required to supply this motion is considerable when compared
16 with a knee which is moving in the vertical direction only, with no sideways motion.

17
18 ——— It is another object and advantage of the present invention to minimize this wasted
19 energy by adding wedges under the cyclist's shoe such that the inside sole of the cyclist's shoe is
20 at the same angle as his natural forefoot angle or cant thus eliminating unnecessary horizontal
21 movement of the knee.

22
23 ——— Another object and advantage of the present invention is the adjustment of the cyclist's
24 shoe to account for the forefoot cant angle, which spreads the pressure generated on the sole of
25 the cyclist's foot when force is applied to the pedal through the sole of the shoe and the cleat in a
26 more optimum and natural manner. The metatarsal heads of the 5 digits will have the correct
27 distribution of load.

1 ~~If the forefoot is forced into the flat position, as in the current art, there is already a~~
2 ~~misalignment of force applied to the foot sole through the metatarsal heads, or the balls of the~~
3 ~~foot, which can cause pain and discomfort in the outer portion of the foot. Cyclists who have~~
4 ~~been fitted with the current art devices which create a flattened forefoot condition on the pedal~~
5 ~~had previously reported their feet 'going to sleep' during cycling. When fitted according to the~~
6 ~~method of the present invention, cyclists have reported greatly improved feet conditions during~~
7 ~~and after a race.~~

8
9 Figure 1 is a cross-sectional view of the pedal device with a pedal spindle bolt (100)
10 connected to a tuning fork (104) by a retaining bolt (102). The tuning fork holds an anchor (106)
11 which has two parallel slots that slide along the inside surfaces (101) of the arms (103) of the
12 tuning fork. Through the center of the anchor is a threaded hole (105) through which threads
13 onto the connecting bolt (108) of the saddle plate (116). An angle indicator (110) is connected
14 to the side of the connecting bolt (108). Above the saddle plate is a cleat adapter (118)
15 connected to the saddle plate (116) by a threaded stud (120) and a nut (122). The cyclist's cleat
16 height is adjusted by turning the connecting bolt (108) to achieve the desired height of the cleat
17 adapter (118). The amount of cant required is set by moving the cleat adapter (118) back and
18 forth in the slot (123) in the cleat adapter. The pedal width is set by sliding the anchor slots
19 (107) along the tuning fork arms (103) until the correct width is established, then locking the
20 position in the tuning fork arms by tightening the retaining bolt through the bolt holes (114).
21 The cyclist's toe-in toe-out position is measured by checking the angle between the indicator
22 (110) and the angle plate (112).

23
24 Figure 2 is a cross-sectional view take along line 2-2 of the pedal device illustrated in
25 Figure 1. The angles (113) on the plastic see-through angle plate (112) are in one degree
26 increments. Details of the slot (124) can be seen sliding on the tuning fork arms (103). The
27 locking bolt (109) fixes the position of the pedal width dimension.

1 Figure 3 shows the location of the various points in the legs that are referenced in the
2 application. The pelvis point (140) is shown as well as the greater trochanter (146), the hip joint
3 (142), the femur (146), the patella (148), the tibial tuberosity (154), the fibula (150), the tibia
4 (152), the subtalar joint (158), the metatarsal heads (160), the forefoot (156) and the second toe
5 (162). These points are used at various stages in the fitting method.

6
7 Figure 4a shows a top view of a handle bar fitting device consisting of a quill clamp
8 (300) with a quill clamp retaining bolt hole (302), into which is inserted a bolt (not shown). The
9 bolt is tightened to hold the device on the quill shaft of the bicycle. A pivot bolt hole (304) is
10 lined up with the center of the quill (303) and allows the device to pivot up and down (311). The
11 reach of the bars is set by moving the side plates (306) fore and aft in the grooves in the side
12 pivot plates (308). A spacing plate (316) maintains the assembly of the device.

13
14 Figure 4b shows a side view of the handle bar fitting device showing the fore-and-aft
15 adjustment bolt (320) which locks the position once found. The side pivot plates (300) have an
16 angle measuring feature consisting of a locking pin (305) and an angle extension (307) which
17 can be adjusted to set the correct angle of the handlebars. An angle pivot bolt (318) allows
18 adjustment of the angle of the side plates (306) and locks it to the correct setting.

19
20 Figures 5a and 5b show details of the special cleat retaining screw (400) consisting of an
21 Allen-head socket (408) and a shoulder section (402) which allows deeper penetration of the
22 Allen-head cavity (406). The threaded section (404) is a standard length. The addition of the
23 shoulder (402) allows a deeper engagement Allen-head socket space which improves
24 engagement of the Allen-head socket lever (not shown) and removes the tendency of the
25 standard industry Allen-head screw to strip the socket when it is tightened in place.

26
27 Figure 6a shows a cyclist's foot (600) positioned on top of a cant angle measuring device
28 (610). The heel (606) of the foot is placed against a back plate (608) and the heel base (604)

1 rests on the top of the device as well as the forefoot (602). The rotation tube (612) of the device
2 allows the angle indicator (616) to move relative to the heel tube (610) as it follows the varus or
3 valgus rotation of the cyclist's foot. The cant angle is indicated to the nearest degree on the
4 angle plate (614).

5
6 Figure 6b shows a front view of the cant angle measuring device and shows the forefoot
7 rotation (618) and the indicator (616) and the relative angle (618) which is the cant angle of the
8 foot.

9
10 The embodiments described above are only one possible example and the invention is not
11 limited to the ones described above and many other variations are possible which will carry out
12 the intent of the invention and method described herein.

13
14 The present invention is not limited to general recreational cycling as described in earlier
15 sections but this type of application was selected to clearly define the invention using one of the
16 many applications. There are many types of bicycles and types of use and all can benefit from
17 the application of the present invention.

18
19 For example, the present invention can be applied with benefit to any sports activity,
20 exercise routine, including weightlifting, aerobics, exercise machine and the like, by proper
21 fitting of the shoe and placement of the hands.

22
23 Further, although the invention as presented addresses the needs of a recreational cyclist,
24 the invention is equally applicable with minor modifications to the special needs of a variety of
25 styles of bicycles and their use. Some of these specialty applications are triathlete and duathlete
26 events in which because cycling is only a portion of the whole event and the cyclist has to
27 perform another strenuous act immediately after cycling, the balance of the values of the various
28 fitting parameters and measurements must be carefully taken into account.

1 Similarly in the case of track pursuit, or any time trial event, spin bike or indoor bike
2 events, downhill mountain bike and BMX or bicycle motocross events, the special needs of each
3 of these types of use can be better optimized by use of the present invention.

4
5 For instance, in triathlon events, the cyclist sits with his or her hips rolled forward as
6 measured by a point on the greater trochanter and a point on the pelvis, placing the upper body in
7 a more horizontal position. In fact the optimum position of the upper body is within (4-7) inches
8 from the horizontal as measured from a line through the pelvis point and the shoulder socket.

9
10 Additionally, special aerobars are added to the handlebars with and without elbow
11 support and the seat height is adjusted to alter the leg angle from the (25-35) degree optimum
12 used for the general cyclist. Further, the seat is moved forward for the triathlete, to achieve a
13 more aerodynamic shape of the cyclist's body in order to minimize drag. The plumb bob
14 described earlier also hangs (1-4) inches ahead of the pedal spindle center line instead of passing
15 through the spindle center.

16
17 In the case of time trial events, the measurements are the same as for a triathlete except
18 that the upper body position is in the (2-4) inch range, the plumb bob is set (1-2) inches forward
19 and the seat is set further forward to help minimize aerodynamic drag. Wind tunnel tests have
20 found that aerodynamic drag is minimized when a plumb line is placed so that it bisects the
21 cyclist's ear, passes down through the vee formed on the upper side of his elbow and when this
22 vee and the base of the cyclist's hands on the handlebars are in a horizontal line.

23
24 In the case of pursuit events, the upper body shoulder is set (-1 to 2) inches above the hip
25 or pelvis point.

26
27 In the case of spin bikes the leg angle is set on the (25-40) degree range and seat and
28 handlebar settings are selected to position the upper body generally a lot higher than the general

1 cyclist. The flip-flop pedal device described earlier can be used to great advantage in this
2 application since it reduces the number of pedals that must be made available to fit the individual
3 cyclist. Since one bicycle is used by many cyclists, with different cleat designs on their shoes,
4 the flip-flop pedal device, being LOOK (road) and SPD (mountain) compatible, greatly reduces
5 the number of pedal changes needed to service this type of public.

6
7 In the case of BMX bikes, the fitting allows for proper sizing of the bike for handling
8 under the extreme terrain conditions and use of the bike that occurs in this type of event.

9
10 In the case of downhill mountain bikes, the seat is generally set lower to lower the center
11 of gravity and improve bike maneuverability and control. Adjustments are also made to improve
12 aerodynamics of the bike/cyclist system.

13
14 The method and devices for fitting a cyclist to a bicycle described herein are compatible
15 with all current manufactured pedal/cleat systems in use today, such as all LOOK (road), SPD
16 (mountain), TIME and SPEEDWAY (road) compatible systems to name a few as well as the
17 traditional toe-clip (basket) and strap design and platform pedals.

18
19 The present invention is an improvement on an earlier flip-flop pedal design, initially
20 disclosed in the inventor's prior application 08/923,022. The flip-flop pedal disclosed therein,
21 has one side of the pedal surface constructed to match a LOOK (road) type or style of shoe cleat
22 and the other side of the pedal surface constructed to match an SPD (mountain) type or style of
23 shoe cleat.

24
25 There are two added features to the invention as part of this continuation-in-part, which
26 accommodate two other pedal/cleat designs developed and sold by the SPEEDPLAY Company,
27 called the SPEEDPLAY (road) X-Pedal and SPEEDPLAY (mountain) Frog Pedal. The
28 SPEEDPLAY (road) types of clip-less bicycle cleat/pedal design variations are similar in

1 operation to LOOK (road) and SPD (mountain), but have their own unique design and
2 operational features and are also in common use today by cyclists. The flip-flop pedal and two
3 extra adapter features to accommodate the two SPEEDPLAY (road/mountain) cleat designs are
4 illustrated in the Figures and described in detail.

5
6 The first of the extra features of the present invention is an adapter plate that attaches to a
7 LOOK (road) style pedal. This first adapter feature allows the cyclist to exercise on a bicycle
8 fitted with either a set of LOOK (road) style pedals or a bicycle fitted with the flip-flop pedals of
9 the present invention, while using cycling shoes fitted with SPEEDPLAY (road) X-pedal type
10 cleats.

11
12 The second extra feature is another adapter plate that also attaches to a bicycle fitted with
13 a LOOK (road) style pedal. This second adapter feature allows the cyclist to exercise on a
14 bicycle fitted with a set of LOOK (road) style pedals or a bicycle fitted with the flip-flop pedals
15 of the present invention, while using cycling shoes fitted with SPEEDPLAY (mountain) Frog
16 Pedal type cleats.

17
18 When either of the two adapters and/or the flip-flop pedals of the present invention are
19 fitted to a bicycle, the majority of cyclists can immediately use the bike as it can now
20 accommodate such a wide variety of shoe cleats. Thus the rider of an exercise bike fitted with
21 the flip-flop pedals and with the two adapter plates available does not have to change the pedals
22 on the exercise bike nor carry bicycle shoes with different cleats than the ones that he normally
23 uses on his own outdoor bicycle. Use of the flip-flop pedals and the two adapters can
24 accommodate the three most popular cleat/pedal combination designs used by cyclists today,
25 namely LOOK (road), SPD (mountain) and both types of SPEEDPLAY (road/mountain), namely
26 the X-Pedal and the Frog pedal.

27
28 The flip-flop pedals and adapters are not limited in use to exercise bikes but can also be

1 used beneficially on a road bike. For instance, in a bicycle race when a bike crashes and cannot
2 be used, the rider can quickly get onto a spare bike fitted with flip-flop pedals, and continue in
3 the race with a minimum of wasted time no matter what cleats he has on his shoes.

4
5 The present invention also addresses the spindle-breaking problem by incorporating a
6 spindle with a larger diameter, thus lowering the stresses imposed on the spindle by the rider on
7 a stationary bike. This stronger spindle will greatly increase the service life of the pedal on the
8 spin bikes used in gyms and exercise clubs.

9
10 Figure 7a is a top view of the LOOK/SPD (road/mountain) flip-flop pedal of the present
11 invention. The top side of the flip-flop pedal is the LOOK (road) style pedal side. This top view
12 shows the front recess (202) that accommodates the front tongue of a LOOK (road) style shoe
13 cleat (224 in Fig. 8a) and the spring-loaded retaining plate (204) that locks in the rear tongue of
14 the LOOK (road) style shoe cleat (226 of Fig. 8a). The threaded pedal spindle (200) attaches the
15 pedal to a bicycle pedal crank (not shown).

16
17 Figure 7b is a side view of a LOOK/SPD (road/mountain) flip-flop pedal, showing the
18 LOOK (road) style side at the top and the SPD (mountain) style side at the bottom. In the case
19 of the LOOK (road) style top side, the retaining plate (204) rotates around a bolt (205) connected
20 to an internal spring (not shown) when force is applied at surface (207) by the shoe cleat rear
21 tongue (226 in Fig. 8a). Once the rear of the shoe cleat falls inside the recess (209) the retaining
22 plate (204) moves back into place, under the action of the spring, thus locking the shoe cleat to
23 the LOOK (road) style pedal surface.

24
25 Figure 7b also shows an SPD (mountain) style cleat attachment on the bottom side of the
26 flip-flop pedal. The front tongue of an SPD (mountain) style shoe cleat (not shown) is first
27 inserted into the locking feature (208), on the SPD (mountain) pedal body (199), then the rear
28 part of the cleat (not shown) pushes against the spring loaded retaining plate (216), causing the

1 plate to move back. The spring (not shown) is held in place by a bolt (211) mounted into the
2 flip-flop pedal body (199). Then the rear of the SPD (mountain) style cleat engages the recess
3 (210) in the rear retaining plate (216). Once in place, the spring-loaded retaining plate (216)
4 moves forward and the cleat is locked tightly onto the flip-flop pedal body (199).

5
6 Figure 7c is a bottom view of the LOOK/SPD (road/mountain) flip-flop pedal showing
7 more details of the SPD (mountain) style pedal. The retaining screws (214, 215) lock the SPD
8 (mountain) style cleat base plate (212) onto the flip-flop pedal body (213).

9
10 Figure 9a is a top view the SPEEDPLAY (road) X-Pedal cleat adapter, which mounts
11 onto the LOOK (road) side of the flip-flop pedal or onto a standard LOOK (road) style pedal.
12 The standard SPEEDPLAY (road) X-Pedal has a 'bow tie' shaped plate (220). In this adapter,
13 the bow tie shaped plate (220) is mounted on top of and integral with a LOOK (road) style cleat
14 shape (229). The bow-tie plate is held in place by two screws (222). The adapter surface (221)
15 and the two recesses (224 and 226) are identical to those on a standard LOOK (road) style cleat
16 as shown in Figures 8a and 8b.

17
18 Figure 9b is a cross-sectional view of the SPEEDPLAY (road) X-Pedal cleat adapter of
19 Figure 10a. The metal bow-tie plate (220) is held in place by two screws (230), which pass
20 through the body of the adapter (231) and are fastened by two nuts (228). When the adapter is
21 mounted onto the LOOK (road) side of the flip-flop pedal, a cyclist wearing a SPEEDPLAY
22 (road) X-Pedal cleat on the sole of his cycling shoe can mount the bike and lock his cleats
23 directly onto the top of the adapter, because the top shape and geometry of the adapter is
24 identical to the top surface of a SPEEDPLAY (road) X-Pedal.

25
26 Figure 9c is a side view of the SPEEDPLAY (road) X-Pedal Cleat Adapter (231) being
27 fitted into the LOOK (road) style side of a flip-flop pedal. Details of the SPD (mountain) side of
28 the flip-flop pedal are not shown for clarity. The front tongue (224 in Figure 9a) of the adapter

1 is first fitted into the recess (202) in the LOOK (road) style side of the flip-flop pedal and the
2 rear section (226) is pushed down onto the spring loaded retaining plate (204). The spring (242)
3 is held in place by a bolt (244) mounted into the body of the pedal. The downward force causes
4 the retaining plate (204) to move backwards and thus allow the rear section of the adapter (231)
5 to fall into the recess (240) and so be locked securely onto the flip-flop pedal.

6
7 Figure 10a is a top of a SPEEDPLAY (mountain) Frog Cleat Adapter, which mounts onto
8 the LOOK (road) side of the flip-flop pedal. A standard Frog (mountain) style pedal has a
9 circular metal ring (256) with two threaded holes (223) which engages the Frog (mountain) style
10 cleat. The top surface of the adapter (262) contains a sloped ramp (258), which allows
11 disengagement of the Frog (mountain) style cleat (not shown), when the cyclist rotates his shoes
12 toward the frame of the bicycle. The Frog (mountain) style pedal metal ring has two lugs (270)
13 that protrude on each side of the metal ring and engage the Frog (mountain) style shoe cleats (not
14 shown), thus fastening the cleats to the pedals.

15
16 Figure 10b is a side view partially sectioned of a SPEEDPLAY Frog (mountain) Cleat
17 Adapter. The front and rear tongues (224, 226) are shown. The retaining bolts (254) pass
18 through the body of the adapter and engage and lock into the two threaded holes (223) in the
19 Frog (mountain) style metal ring (256). The front ramp (258 in Figure 10a) has a flat vertical
20 side (260) that blocks the Frog (mountain) style shoe cleat, and stops it from disengaging, when
21 the rider rotates his shoes away from the bicycle frame.

22
23 ~~Figure 11 is a view of a prior art INSTEP LOOK (road) style Pedal Adapter. The adapter~~
24 ~~body (300) is similar in shape to a standard LOOK (road) style cleat (Figures 8a and 8b), with a~~
25 ~~front tongue (306) and a rear tongue (305) identical to the front and rear tongues of a LOOK~~
26 ~~(road) style cleat. Thus the INSTEP (road) adapter can be locked onto a LOOK (road) style~~
27 ~~pedal. The toe-straps (301) are connected to an arch strap (302) through a common connector~~
28 ~~plate (307). The arch strap (302) is attached to the adapter body (300) in an adjustable manner~~

1 ~~(not shown). The cyclist inserts his running shoe into the cage consisting of the toe-straps and~~
2 ~~the arch strap and the upper surface (308) of the adapter base (300), thus forming an attachment~~
3 ~~between his running shoe and the INSTEP (road) adapter, which in turn, is connected to the~~
4 ~~pedal.~~

5
6 Described briefly, the present invention is a unique and novel flip-flop bicycle pedal that
7 utilizes both sides of the pedal such that one side correspondingly matches with a prior art road
8 type pedal configuration known in the art as LOOK pedal and the other side correspondingly
9 matches with another prior art mountain type pedal configuration known in the art as SPD pedal.
10 Alternatively, the present invention is a plurality of unique pedal adapters that utilize
11 conventional type bicycle pedal configurations which complementary match a plurality of prior
12 art bicycle shoe cleats known in the art as LOOK cleat, SPD cleat, SPEEDPLAY "X" cleat,
13 SPEEDPLAY frog cleat, and BE-BOP cleat.

14
15 ~~Referring to Figure 12, there is shown a prior art of a first conventional type bicycle~~
16 ~~pedal 500 which is known in the art as LOOK bicycle pedal. This first prior art bicycle pedal~~
17 ~~500 includes a toe or first retaining section 501, a rear or second spring-loaded plate 502 and a~~
18 ~~threaded spindle connector 503 which is connected to the bicycle pedal crank (not shown). The~~
19 ~~toe retaining section 501 holds the front 224 of a prior art of a first conventional type shoe cleat~~
20 ~~(see Figure 8a) while the rear spring-loaded plate 502 moves away from the body of the pedal~~
21 ~~when the first prior art shoe cleat is inserted and the rear spring-loaded plate snaps back to lock~~
22 ~~the shoe cleat on the pedal 500.~~

23
24 ~~Referring to Figures 13 and 14, there is shown a prior art of a second conventional type~~
25 ~~bicycle pedal 504 which is known in the art as SPD bicycle pedal. This second prior art bicycle~~
26 ~~pedal 504 includes a front tongue recess 505, a rear tongue spring-loaded plate 506 and a~~
27 ~~threaded spindle connector 507 which is connected to the bicycle pedal crank (not shown). The~~
28 ~~spring-loaded retaining plate 506 is held in place by a winding spring 508 and secured to the~~

1 body of the pedal 504 by a bolt 509. Referring to Figure 23, a front tongue 512 of a second prior
2 art type shoe cleat 510 is first inserted into the front tongue recess 505 and then the rear tongue
3 514 of the second prior art shoe cleat 510 pushes against the spring-loaded plate 506, causing the
4 plate 506 to move away from the body of the pedal and once in place the spring-loaded retaining
5 plate 506 moves back into position and securely locks the shoe cleat to the pedal 504.

6
7 — Referring to Figure 15, there is shown a prior art of a third conventional type bicycle
8 pedal 516 which is known in the art as SPEEDPLAY "X" bicycle pedal. This second prior art
9 bicycle pedal 516 includes a circular base 518, a metal bow-tie shaped plate 520 which is
10 mounted to the base 518 and held by two screws 522, two grooves 524 located on opposites and
11 parallel to a threaded spindle connector 526 which is connected to the bicycle pedal crank (not
12 shown). Referring to Figure 24, there is shown a prior art of a third conventional type shoe cleat
13 528 which correspondingly matches with the third prior art bicycle pedal 516. The shoe cleat
14 528 includes a circular shaped recess 530 which correspondingly matches the circular base 518
15 of the third prior art bicycle pedal 516 and two opposite parallel rods 532 almost extending the
16 diameter of the recess 530. The third prior art shoe cleat is positioned onto of the third prior art
17 bicycle pedal 516 such that the recess 530 encompass the base 518 and then the two parallel rods
18 532 engage with the two grooves 524 to secure the third prior art shoe cleat 528 to the third prior
19 art pedal 516.

20
21 — Referring to Figure 16, there is shown a prior art of a fourth conventional type bicycle
22 pedal 534 which is known in the art as SPEEDPLAY frog bicycle pedal. This fourth prior art
23 bicycle pedal 534 includes a circular metal ring 536 mounted and secured to a protruding base
24 538 by two screws 540, and a threaded spindle connector 537 which is connected to the bicycle
25 pedal crank (not shown). A sloped ramp 542 is formed with the protruding base 538, which
26 allows disengagement of the fourth prior art shoe cleat 544 shown in Figure 25. When the
27 cyclist rotates his or her shoe toward the bicycle's frame, two protruding lugs 546 on each side
28 of the metal ring 536 are engaged by a pair of retaining flanges 548 to secure the fourth prior art

1 shoe cleat 544 (see Figure 25) thereto. A stopping flange 550 is also provided and engages with
2 the sloped ramp 543 to stop the rotation of the fourth prior art shoe cleat 544, thereby fastening
3 the fourth prior art shoe cleat to the fourth prior art bicycle pedal.

4
5 — Referring to Figure 17, there is shown a prior art of a fifth conventional type bicycle
6 pedal 552 which is known in the art as BE-BOP bicycle pedal. This fifth prior art bicycle pedal
7 552 includes a pair of spaced apart opposite generally circular flanges 554 which form the
8 attachment mechanism of the pedal, and a threaded spindle connector 547 which is connected to
9 the bicycle pedal crank (not shown) and sandwiched between the circular flanges 554. Referring
10 to Figure 26, there is shown a prior art of a fifth conventional type shoe cleat 556 which
11 correspondingly matches with the fifth prior art bicycle pedal 552. The shoe cleat 556 includes a
12 circular shaped recess 558 which correspondingly matches with either one of the pair of circular
13 flanges 554 of the fifth prior art bicycle pedal 552. The fifth prior art shoe cleat 552 is
14 positioned onto of the fifth prior art bicycle pedal 516 such that the two opposite flanges 560
15 engage with the circular flange 554 of the fifth prior art bicycle pedal to secure the fifth prior art
16 shoe cleat 556 to the fifth prior art pedal 552.

17
18 Referring to Figures 7a, 7b, 7c, 18, 19, 20, 21 and 22, there is shown at 570 the present
19 invention flip-flop bicycle pedal. The present invention flip-flop bicycle pedal 570 is a
20 combination of the first prior art bicycle pedal 500 (see Figure 12) and the second prior art
21 bicycle pedal 504 (see Figures 13 and 14). The flip-flip flop bicycle pedal 570 comprises a main
22 body 199 and a threaded spindle bolt or connector 200 which is threadedly connected to a
23 bicycle pedal crank (not shown), where the main body 199 is pivotable about a transverse axis
24 574 of the bicycle. The main body 199 has a top or first side 576 and a bottom or second side
25 578. The top side 576 is similarly configured with the first prior art bicycle pedal 500 (see
26 Figure 12) and includes a toe cleat clamping mechanism which has a front recess 202 for
27 receiving the front tongue 224 of the first prior art shoe cleat (see Figures 8a and 8b), a rear
28 spring-loaded plate 204 pivotably connected to the main body 199 by a bolt 205 and an internal

1 spring 580 wound around the bolt 205. When a force is applied at a surface 207 by the first prior
2 art shoe cleat (see Figure 19 and shown in dashed lines), the spring-loaded plate 204 moves
3 away from the main body 199 such that the rear tongue 226 (see Figure 20 and shown in dashed
4 lines) of the first prior art shoe cleat falls inside the recess 209 and the spring-loaded plate 204
5 springs back into a locking position, thereby locking the first prior art shoe cleat to the top side
6 of the main body 199 of the flip-flop pedal 570.

7
8 The bottom side 578 of the flip-flop bicycle pedal 570 is similarly configured with the
9 second prior art bicycle pedal 504 (see Figures 13 and 14) and includes a toe cleat clamping
10 plate or mechanism 212 which is smaller than the toe cleat clamping mechanism located on the
11 top side 576. The toe cleat clamping mechanism 212 is mounted to the main body 199 by
12 retaining screws 214 and 215 (see Figure 18). The front tongue 512 of the second prior art shoe
13 cleat 510 (see Figure 23) is first inserted into the locking feature 208 while the rear tongue 514
14 engages with and pushes against the spring-loaded retaining plate 216 (see Figure 21 and shown
15 in dashed lines) causing the spring-loaded plate 216 to move back (see Figure 22 and shown in
16 dashed lines). A spring 582 is held in place by a bolt 211 (see Figure 7b) mounted in the main
17 body 199 of the flip-flop bicycle pedal 570. The spring 582 is wound around the bolt 211.
18 When a force is applied on the spring-loaded plate 216 by the second prior art shoe cleat (see
19 Figure 21 and shown in dashed lines), the spring-loaded plate 216 moves away from the main
20 body 199 (see Figure 22 and shown in dashed lines) such that the rear tongue 514 of the second
21 prior art shoe cleat 510 falls inside the recess 210 and the spring-loaded plate 216 springs back
22 into a locking position, thereby locking the second prior art shoe cleat 510 to the bottom side 578
23 of the main body 199 of the flip-flop pedal 570.

24
25 Referring to Figures 27 and 28, alternatively, there is shown at 590 an alternative
26 embodiment of the present invention pedal adapter shown in Figures 9a, 9b, 9c, 10a, and 10b. In
27 this embodiment, the pedal adapter 590 is a combination of the first prior art shoe cleat (see
28 Figure 8a) and the fifth prior art bicycle pedal 552. The pedal adapter 590 can be used with the

1 present invention flip-flop bicycle pedal 570 or the first prior art bicycle pedal 500 (see Figure
2 12).

3
4 It will be appreciated that the present invention is not limited to the use of the flip-flop
5 bicycle pedal discussed in this application. It is emphasized that while the present invention
6 pedal adapter is preferredly used with the flip-flop bicycle pedal, it is also within the spirit and
7 scope of the present invention to utilize it with the first prior art bicycle pedal shown in Figure
8 12. The following description will be related to the flip-flop bicycle pedal 570.

9
10 In this pedal adapter 590, the circular flange 554 which is identical to the circular flange
11 554 shown in Figure 17 is attached to the top of the first prior art shoe cleat as shown. The front
12 tongue 224 of the pedal adapter 590 is first fitted into the recess 202 of the flip-flop bicycle
13 pedal 570 (see Figure 7a, 7b, 18, 19, and 20) while the rear tongue 226 pushes down onto the
14 spring loaded retaining plate 204. The downwards force causes the retaining plate 204 to move
15 away from the body of the pedal and the rear tongue 226 of the adapter 590 to fall into the recess
16 209 and thereby locks the adapter 590 to the flip-flop pedal 570.

17
18 The cyclist wearing the fifth prior art shoe cleat 556 (see Figure 26) can then mount his
19 or her shoe cleat 556 to the circular flange 554 of the pedal adapter 590, thereby securing the
20 shoe cleat to the pedal adapter as discussed above.

21
22 Referring to Figures 9a, 9b and 9c, there is shown a preferred embodiment of the present
23 invention pedal adapter. In this embodiment, the pedal adapter is a combination of the first prior
24 art shoe cleat (see Figure 8a) and the third prior art bicycle pedal 516 (see Figure 15). The pedal
25 adapter can be used with the present invention flip-flop bicycle pedal 570 or the first prior art
26 bicycle pedal 500 (see Figure 12).

27
28 It will be appreciated that the present invention is not limited to the use of the flip-flop

bicycle pedal discussed in this application. It is emphasized that while the present invention pedal adapter is preferredly used with the flip-flop bicycle pedal, it is also within the spirit and scope of the present invention to utilize it with the first prior art bicycle pedal shown in Figure 12. The following description will be related to the flip-flop bicycle pedal 570.

In this pedal adapter, the bow tie plate 220 is identical to the bow tie plate 520 of the third prior art bicycle pedal 516 (see Figure 15) and is mounted on top of and integral with the shoe cleat. The surface 221 and the two tongues 224 and 226 are identical to those on the first prior art shoe cleat as shown in Figures 8a and 8b. The front tongue 224 of the pedal adapter is first fitted into the recess 202 of the flip-flop bicycle pedal 570 (see Figure 7a, 7b, 18, 19, and 20) while the rear tongue 226 pushes down onto the spring loaded retaining plate 204. The downward force causes the retaining plate 204 to move away from the body of the pedal and the rear tongue 226 of the adapter to fall into the recess 209 and thereby locks the adapter 590 to the flip-flop pedal 570.

The cyclist wearing the third prior art shoe cleat 528 (see Figure 24) can then mount his or her shoe cleat 528 such that the recess 530 encompasses the plate 220 and then the two rods 532 engage with grooves to secure the third prior art shoe cleat 528 to the pedal adapter as discussed above.

Referring to Figures 10a and 10b, there is shown another alternative embodiment of the present invention pedal adapter. In this embodiment, the pedal adapter is a combination of the first prior art shoe cleat (see Figure 8a) and the fourth prior art bicycle pedal 534 (see Figure 16). The pedal adapter can be used with the present invention flip-flop bicycle pedal 570 or the first prior art bicycle pedal 500 (see Figure 12).

It will be appreciated that the present invention is not limited to the use of the flip-flop bicycle pedal discussed in this application. It is emphasized that while the present invention

pedal adapter is preferredly used with the flip-flop bicycle pedal, it is also within the spirit and scope of the present invention to utilize it with the first prior art bicycle pedal shown in Figure 12. The following description will be related to the flip-flop bicycle pedal 570.

In this pedal adapter, the upper portion of the pedal adapter is identical to the fourth prior art bicycle pedal 534 discussed in Figure 16, and the description thereof will not be repeated.

When in use, the front tongue 224 of the pedal adapter is first fitted into the recess 202 of the flip-flop bicycle pedal 570 (see Figure 7a, 7b, 18, 19, and 20) while the rear tongue 226 pushes down onto the spring loaded retaining plate 204. The downward force causes the retaining plate 204 to move away from the body of the pedal and the rear tongue 226 of the adapter to fall into the recess 209 and thereby locks the adapter 590 to the flip-flop pedal 570.

The cyclist wearing the fourth prior art shoe cleat 544 (see Figure 25) can then mount his or her shoe cleat 544 such that when the cyclist rotates his or her shoe toward the bicycle's frame, two protruding lugs 270 on each side of the metal ring 256 are engaged by a pair of retaining flanges 548 to secure the fourth prior art shoe cleat 544 thereto. A stopping flange 550 is also provided and engages with the sloped ramp 258 to stop the rotation of the fourth prior art shoe cleat 544, thereby fastening the fourth prior art shoe cleat to the pedal adapter.

~~Defined in detail, the present invention is a flip-flop bicycle pedal, comprising: (a) a main body pivotable about a transverse axis and having a spindle bolt for connecting to a bicycle, a top side and a bottom side; (b) the top side having a toe cleat clamp which conforms to a bottom of a road type bicycle shoe cleat, the toe cleat clamp having a front recess for receiving a front tongue of the road type bicycle shoe cleat and a rear spring-loaded retaining plate pivotable on the main body, the rear spring-loaded retaining plate having a recess for receiving a rear tongue of the road type bicycle shoe cleat and when a force is applied to the spring-loaded retaining plate, the spring-loaded retaining plate moves away from the main body such that the~~

1 rear tongue engages the recess of the spring-loaded retaining plate, where the spring-loaded
2 retaining plate springs back into a locking position, and thereby locks the rear tongue of the road
3 type bicycle shoe cleat thereto; and (c) the bottom side having a toe cleat clamp which is smaller
4 than the toe cleat clamp of the top side and conforms to a bottom of a mountain bicycle type
5 shoe cleat, the toe cleat clamp of the bottom side having a front locking member located adjacent
6 to the rear spring-loaded retaining plate of the top side for receiving a front tongue of the
7 mountain bicycle type shoe cleat and a rear spring-loaded retaining member pivotable on the
8 main body such that a rear tongue of the mountain bicycle type shoe cleat engages inside a
9 recess of the rear spring-loaded retaining plate of the bottom side, where the rear spring-loaded
10 plate of the bottom side springs back into a locking position, and thereby locks the rear tongue of
11 the mountain bicycle type shoe cleat thereto.

12
13 ——— Defined broadly, the present invention is a bicycle pedal, comprising: (a) a main body
14 pivotable about a transverse axis and having a spindle bolt for connecting to a bicycle, a first
15 cleat clamp side and a second cleat clamp side; (b) the first cleat clamp side conforming to a
16 bottom of a bicycle road shoe cleat and having a recess for receiving a first tongue of the road
17 shoe cleat and a spring-loaded retaining plate pivotable on the main body for receiving a second
18 tongue of the road shoe cleat and when a force is applied to the spring-loaded retaining plate, the
19 spring-loaded retaining plate moves away from the main body such that the second tongue
20 engages the spring-loaded retaining plate, where the spring-loaded retaining plate springs back
21 into a locking position, and thereby locks the second tongue of the road shoe cleat thereto; and
22 (c) the second cleat clamp side being smaller than the top cleat clamp side and conforming to a
23 bottom of a mountain bicycle type shoe cleat, the second cleat clamp side having a locking
24 member located adjacent to the spring-loaded retaining plate of the top side for receiving a first
25 tongue of the mountain bicycle type shoe cleat and a spring-loaded retaining member pivotable
26 on the main body such that a second tongue of the mountain bicycle type shoe cleat engages the
27 spring-loaded retaining member of the second side, where the spring-loaded retaining member of
28 the second side springs back into a locking position, and thereby locks the second tongue of the

1 mountain bicycle type shoe cleat thereto.

2
3 ~~Defined more broadly, the present invention is a bicycle pedal, comprising: (a) a main~~
4 ~~body pivotable about a transverse axis and having a spindle bolt for connecting to a bicycle, a~~
5 ~~first side and a second side; (b) the first side conforming to a bottom of a bicycle road shoe cleat~~
6 ~~and having means for receiving a first tongue of the road shoe cleat and a spring-loaded retaining~~
7 ~~plate pivotable on the main body for receiving a second tongue of the road shoe cleat and when a~~
8 ~~force is applied to the spring-loaded retaining plate, the spring-loaded retaining plate moves~~
9 ~~away from the main body such that the second tongue is retained within the spring-loaded~~
10 ~~retaining plate, where the spring-loaded retaining plate moves back into a locking position, and~~
11 ~~thereby locks the second tongue of the road shoe cleat thereto; and (c) the second side~~
12 ~~conforming to a bottom of a mountain bicycle shoe cleat and having a locking member for~~
13 ~~receiving a first tongue of the mountain bicycle shoe cleat and a spring-loaded retaining member~~
14 ~~pivotable on the main body such that a second tongue of the mountain bicycle shoe cleat is~~
15 ~~retained within the spring-loaded retaining member of the second side, where the spring-loaded~~
16 ~~retaining member of the second side moves back into a locking position, and thereby locks the~~
17 ~~second tongue of the mountain bicycle shoe cleat thereto.~~

18
19 Defined in detail, the present invention is a flip-flop bicycle pedal, comprising: (a) a
20 main body pivotable about a transverse axis and having a spindle bolt for connecting to a
21 bicycle, a top side and a bottom side; (b) said top side having a first top toe cleat clamp which
22 conforms to a bottom of a road type bicycle shoe cleat, the first top toe cleat clamp having a
23 front recess for receiving a front tongue of the road type bicycle shoe cleat, said top side also
24 having a first top rear spring-loaded retaining plate pivotable on said main body, the first top rear
25 spring-loaded retaining plate having a recess for receiving a rear tongue of the road type bicycle
26 shoe cleat and when a force is applied to the first top rear spring-loaded retaining plate, the first
27 top rear spring-loaded retaining plate moves away from said main body such that the rear tongue
28 engages the recess of the first top rear spring-loaded retaining plate, where the first top rear

1 spring-loaded retaining plate springs back into a locking position, and thereby locks the rear
2 tongue of the road type bicycle shoe cleat thereto; and (c) said bottom side having a second
3 bottom toe cleat clamp which is smaller than said first top toe cleat clamp of said top side and
4 conforms to a bottom of a mountain bicycle type shoe cleat, the second bottom toe cleat clamp
5 of said bottom side having a front locking member located adjacent to said front top rear spring-
6 loaded retaining plate of said top side for receiving a front tongue of the mountain bicycle type
7 shoe cleat, said bottom side also having a second bottom rear spring-loaded retaining member
8 pivotal on said main body such that a rear tongue of the mountain bicycle type shoe cleat
9 engages inside a recess of the second bottom rear spring-loaded retaining plate of said bottom
10 side, where the second bottom rear spring-loaded plate of said bottom side springs back into a
11 locking position, and thereby locks the rear tongue of the mountain bicycle type shoe cleat
12 thereto.

13
14 Defined broadly, the present invention is a bicycle pedal, comprising: (a) a main body
15 pivotal about a transverse axis and having a spindle bolt for connecting to a bicycle, a first
16 cleat clamp side and a second cleat clamp side; (b) said first cleat clamp side conforming to a
17 bottom of a road type bicycle shoe cleat and having a recess for receiving a first tongue of the
18 road type bicycle shoe cleat, said first cleat clamp side also having a first spring-loaded retaining
19 plate pivotal on said main body for receiving a second tongue of the road type bicycle shoe
20 cleat and when a force is applied to the first spring-loaded retaining plate, the first spring-loaded
21 retaining plate moves away from said main body such that the second tongue engages the first
22 spring-loaded retaining plate, where the first spring-loaded retaining plate springs back into a
23 locking position, and thereby locks the second tongue of the road type bicycle shoe cleat thereto;
24 and (c) said second cleat clamp side being smaller than said first cleat clamp side and
25 conforming to a bottom of a mountain bicycle type shoe cleat, said second cleat clamp side
26 having a locking member located adjacent to said first spring-loaded retaining plate of said first
27 cleat clamp side for receiving a first tongue of the mountain bicycle type shoe cleat, said second
28 cleat clamp side also having a second spring-loaded retaining member pivotal on said main

1 body such that a second tongue of the mountain bicycle type shoe cleat engages the second
2 spring-loaded retaining member of said second cleat clamp side, where the second spring-loaded
3 retaining member of said second cleat clamp side springs back into a locking position, and
4 thereby locks the second tongue of the mountain bicycle type shoe cleat thereto.

5
6 Defined more broadly, the present invention is a bicycle pedal, comprising: (a) a main
7 body pivotable about a transverse axis and having a spindle bolt for connecting to a bicycle, a
8 first side and a second side; (b) said first side conforming to a bottom of a road type bicycle shoe
9 cleat and having means for receiving a first tongue of the road type bicycle shoe cleat, said first
10 side also having a first spring-loaded retaining plate pivotable on the main body for receiving a
11 second tongue of the road type bicycle shoe cleat and when a force is applied to the first spring-
12 loaded retaining plate, the first spring-loaded retaining plate moves away from said main body
13 such that the second tongue is retained within the spring-loaded retaining plate, where the first
14 spring-loaded retaining plate moves back into a locking position, and thereby locks the second
15 tongue of the road type bicycle shoe cleat thereto; and (c) said second side conforming to a
16 bottom of a mountain bicycle type shoe cleat and having a locking member for receiving a first
17 tongue of the mountain bicycle type shoe cleat, said second side also having a second spring-
18 loaded retaining member pivotable on said main body such that a second tongue of the mountain
19 bicycle type shoe cleat is retained within the second spring-loaded retaining member of said
20 second side, where the second spring-loaded retaining member of said second side moves back
21 into a locking position, and thereby locks the second tongue of the mountain bicycle type shoe
22 cleat thereto.

23
24 Of course the present invention is not intended to be restricted to any particular form or
25 arrangement, or any specific embodiment, or any specific use, disclosed herein, since the same
26 may be modified in various particulars or relations without departing from the spirit or scope of
27 the claimed invention hereinabove shown and described of which the apparatus or method
28 shown is intended only for illustration and disclosure of an operative embodiment and not to

1 show all of the various forms or modifications in which this invention might be embodied or
2 operated.

3
4 The present invention has been described in considerable detail in order to comply with
5 the patent laws by providing full public disclosure of at least one of its forms. However, such
6 detailed description is not intended in any way to limit the broad features or principles of the
7 present invention, or the scope of the patent to be granted. Therefore, the invention is to be
8 limited only by the scope of the appended claims.
